Abstract. We study the problems LOCATING-DOMINATING SET and METRIC DIMENSION, which consist in determining a minimum-size set of vertices that distinguishes the vertices of a graph using either neighbourhoods or distances. We consider these problems when restricted to interval graphs and permutation graphs. We prove that both decision problems are NP-complete, even for graphs that are at the same time interval graphs and permutation graphs and have diameter 2. While LOCATING-DOMINATING SET parameterized by solution size is trivially fixed-parameter-tractable, it is known that METRIC DIMENSION is $W[2]$ -hard. We show that for interval graphs, this parameterization of METRIC DIMENSION is fixed-parameter-tractable.

1 Introduction

Combinatorial identification problems have been widely studied in various contexts. The common characteristic of these problems is that we are given a combinatorial structure, and we wish to distinguish (i.e. uniquely identify) its elements by the means of a small set of selected elements. In this paper, we study two such identification problems where the instances are graphs. In the LOCATING-DOMINATING SET problem, we ask for a dominating set S such that the vertices outside of S are distinguished by their neighbourhood within S . In METRIC DIMENSION, we wish to select a set S of vertices of a graph G such that every vertex of G is uniquely identified by its distances to the vertices of S .

^{*} This is a short version of the full paper [15] available on arXiv:1405.2424.

^{**} Partially supported by the EPSRC Grant EP/K022660/1.

These problems have been extensively studied since their introduction in the 1970s and 1980s. They have been applied to various areas such as network verification [2], fault-detection in networks [34], graph isomorphism testing [1] or the logical definability of graphs [24].

Important concepts and definitions. All considered graphs are finite and simple. We denote by $N[v]$, the *closed neighbourhood* of vertex v , and by $N(v)$ its *open neighbourhood*, i.e. $N[v] \setminus \{v\}$. A vertex is *universal* if it is adjacent to all the vertices of the graph. A set S of vertices of G is a *dominating set* if for every vertex v , there is a vertex x in $S \cap N[v]$. In the context of dominating sets we say that a vertex x *separates* two distinct vertices u, v if it dominates exactly one of them. Set S separates the vertices of a set X if all pairs of X are separated by a vertex of S . The distance between two vertices u, v is denoted $d(u, v)$. The following two definitions are the main concepts studied in this paper.

- (Slater [31,32]) A set L of vertices of a graph G is a *locating-dominating set* if it is a dominating set and it separates the vertices of $V(G) \setminus L$.
- (Harary and Melter [19], Slater [30]) A set R of vertices of a graph G is a *resolving set* if for each pair u, v of distinct vertices, there is a vertex x of R with $d(x, u) \neq d(x, v)$.

The smallest size of a locating-dominating set of G is the *location-domination number* of G , denoted $\gamma^{\text{LD}}(G)$. The smallest size of a resolving set of G is the *metric dimension* of G , denoted $\dim(G)$. The inequality $\dim(G) \leq \gamma^{\text{LD}}(G)$, relating these notions, holds for every graph G . If G has diameter 2, the two concepts are almost the same, as then, one can check that $\gamma^{\text{LD}}(G) \leq \dim(G) + 1$ holds. We consider the two associated decision problems:

LOCATING-DOMINATING SET

Instance: A graph G , an integer k .

Question: Is it true that $\gamma^{\text{LD}}(G) \leq k$?

METRIC DIMENSION

Instance: A graph G , an integer k .

Question: Is it true that $\dim(G) \leq k$?

We will study these problems on interval graphs and permutation graphs, which are classic graph classes that have many applications and are widely studied. They can be recognized efficiently, and many problems can be solved efficiently for graphs in these classes (see e.g. the book by Golumbic [17]). Given a set S of (geometric) objects, the *intersection graph* G of S is the graph whose vertices are associated to the elements of S and where two vertices are adjacent if and only if the corresponding elements of S intersect. Then, S is called an *intersection model* of G . An *interval graph* is the intersection graph of a set of (closed) intervals of the real line. Given two parallel lines B and T , a *permutation graph* is the intersection graph of segments of the plane which have one endpoint on B and the other endpoint on T .

Previous work. The complexity of distinguishing problems has been studied by many authors. LOCATING-DOMINATING SET was first proved to be NP-complete in [7], a result extended to bipartite graphs in [5]. This was improved to planar bipartite unit disk graphs [27] and to planar bipartite subcubic graphs [13]. LOCATING-DOMINATING SET is hard to approximate within any $o(\log n)$ factor (n is the order of the graph), with no restriction on the input graph [33]. This re-

sult was extended to bipartite graphs, split graphs and co-bipartite graphs [13]. On the positive side, LOCATING-DOMINATING SET is constant-factor approximable for bounded degree graphs [18], line graphs [13,14], interval graphs [4] and is linear-time solvable for graphs of bounded clique-width (using Courcelle's theorem [8]). Furthermore, an explicit linear-time algorithm solving LOCATING-DOMINATING SET on trees is known [31].

METRIC DIMENSION, which has a non-local and more intricate flavour, was widely studied as well, and has (re)gained a lot of attention within the last few years. It was shown NP-complete in [16, Problem GT61]. This result has recently been extended to bipartite graphs, co-bipartite graphs, split graphs and line graphs of bipartite graphs [11], to a special subclass of unit disk graphs [22], and to planar graphs [9]. Polynomial-time algorithms for the weighted version of METRIC DIMENSION for paths, cycles, trees, graphs of bounded cyclomatic number, cographs and partial wheels were given in [11]. A polynomial-time algorithm for outerplanar graphs was designed in [9]. It was shown in [2] that METRIC DIMENSION is hard to approximate within any $o(\log n)$ factor for graphs of order n . This is even true for bipartite subcubic graphs, as shown in [20,21].

In light of these results, the complexity of LOCATING-DOMINATING SET and METRIC DIMENSION for interval and permutation graphs is a natural open question (as posed in [26] and [11] for METRIC DIMENSION on interval graphs), since these classes are standard candidates for designing efficient algorithms.

Let us say a few words about the parameterized complexity of these problems. For standard definitions and concepts in parameterized complexity, we refer to the books [10,28]. It is known that for LOCATING-DOMINATING SET, any graph of order n and solution size k satisfies $n \leq 2^k + k - 1$ [32]. Therefore, when parameterized by k , LOCATING-DOMINATING SET is trivially fixed-parameter-tractable (FPT): first check whether the above inequality holds (if not, return “no”), and if yes, use a brute-force algorithm checking all possible subsets of vertices. This is an FPT algorithm. However, METRIC DIMENSION (again parameterized by solution size k) is W[2]-hard even for bipartite subcubic graphs [20,21]. Remarkably, the bound $n \leq D^k + k$ holds [6] (where n is the graph's order, D its diameter, and k is the size of a resolving set). Hence, for graphs of diameter bounded by a function of k , the same arguments as the previous ones yield an FPT algorithm for METRIC DIMENSION. This holds, for example, for the class of (connected) split graphs, which have diameter at most 3. Besides this, as remarked in [21], no standard class of graphs for which METRIC DIMENSION is FPT was previously known.

Our results. We settle the complexity of LOCATING-DOMINATING SET and METRIC DIMENSION on interval and permutation graphs, showing that the two problems are NP-complete even for graphs that are at the same time interval graphs and permutation graphs and have diameter 2 (Section 2). Then, we present a dynamic programming algorithm (using path-decomposition) to solve METRIC DIMENSION in FPT time on interval graphs (Section 3). Up to our knowledge, this is the first nontrivial FPT algorithm for this problem.

2 Hardness results

We will now reduce 3-DIMENSIONAL MATCHING, which is a classic NP-complete problem [23], to LOCATING-DOMINATING SET on interval graphs.

3-DIMENSIONAL MATCHING

Instance: Three disjoint sets A , B and C each of size n , and a set \mathcal{T} of m triples of $A \times B \times C$.

Question: Is there a perfect 3-dimensional matching $\mathcal{M} \subseteq \mathcal{T}$ of the hypergraph $(A \cup B \cup C, \mathcal{T})$, i.e. a set of disjoint triples of \mathcal{T} such that each element of $A \cup B \cup C$ belongs to exactly one of the triples?

2.1 Preliminaries and gadgets

We first define the following *dominating gadget* (a path on four vertices). The idea is to ensure that specific vertices are dominated locally, and therefore separated from the rest of the graph. We will use it extensively. The reduction is described as an interval graph, but we then show that it is also a permutation graph.

Definition 1 (Domingating gadget). A dominating gadget D is a subgraph of an interval graph G inducing a path on four vertices, and such that each interval of $V(G) \setminus V(D)$ either contains all intervals of $V(D)$ or does not intersect any.

In the following, a dominating gadget will be represented as in Figure 1(a).

Fig. 1. Representations of dominating gadget and choice pair.

The proof of the following claim is easy and can be found in Appendix A.1.

Claim 2. If G is an interval graph containing a dominating gadget D and S is a locating-dominating set of G , then $|S \cap V(D)| \geq 2$. Moreover, there is a locating-dominating set S_D of D (called standard solution for D) with $|S_D| = 2$ such that no vertex of D is dominated by all the vertices of S_D . If S is an optimal locating-dominating set, then replacing $S \cap V(D)$ by the standard solution S_D , one can obtain an optimal locating-dominating set S' .

Definition 3 (Choice pair). A pair $\{u, v\}$ of intervals is called a choice pair if u, v both contain the intervals of a common dominating gadget (denoted $D(uv)$), and such that none of u, v contains the other.

See Figure 1(b) for an illustration of a choice pair. Intuitively, a choice pair gives us the choice of separating it from the left or from the right: since none of u, v is included in the other, the intervals intersecting u but not v can only be located at one side of u ; the same holds for v . In our construction, we will make sure that, except for the choice pairs, all pairs of intervals will be easily separated using domination gadgets. Our aim will then be to separate the choice pairs. We have the following claim that follows directly from Claim 2:

Claim 4. *Let S be a locating-dominating set of a graph G and $\{u, v\}$ be a choice pair in G . If the solution $S \cap V(D(uv))$ for the dominating gadget $D(uv)$ is the standard solution S_D , both vertices u and v are dominated, separated from all vertices in $D(uv)$ and from all vertices not intersecting $D(uv)$.*

We now define the central gadget of the reduction, the *transmitter gadget*. Roughly speaking, it allows to transmit information across an interval graph.

Definition 5 (Transmitter gadget). *Let P be a set of two or three choice pairs in an interval graph G . A transmitter gadget $Tr(P)$ is a subgraph of G consisting of a path on seven vertices $\{u, uv^1, uv^2, v, vw^1, vw^2, w\}$ and five dominating gadgets $D(u), D(uv), D(v), D(vw), D(w)$ such that the following properties are satisfied:*

- u and w are the only vertices of $Tr(P)$ that separate the pairs of P .
- The intervals of the dominating gadget $D(u)$ (resp. $D(v), D(w)$) are included in interval u (resp. v, w) and no interval of $Tr(P)$ other than u (resp. v, w) intersects $D(u)$ (resp. $D(v), D(w)$).
- Pair $\{uv^1, uv^2\}$ is a choice pair and no interval of $V(Tr(P)) \setminus (D(uv^1, uv^2) \cup \{uv^1, uv^2\})$ intersects both intervals of the pair. The same holds for pair $\{vw^1, vw^2\}$.
- The choice pairs $\{uv^1, uv^2\}$ and $\{vw^1, vw^2\}$ cannot be separated by intervals of G other than u, v and w .

Figure 2 illustrates a transmitter gadget and shows the succinct graphical representation that we will use. As shown in the figure, we may use a “box” to denote $Tr(P)$. This box does not include the choice pairs of P but indicates where they are situated. Note that the middle pair $\{y_1, y_2\}$ could also be separated (from the left) by u instead of w , or it may not exist at all.

The following claim, proved in Appendix A.1, shows how transmitter gadgets will be used in the main reduction.

Claim 6. *Let G be an interval graph with a transmitter gadget $Tr(P)$ and let S be a locating-dominating set of G . We have $|S \cap Tr(P)| \geq 11$ and if $|S \cap Tr(P)| = 11$, no pair of P is separated by a vertex in $S \cap Tr(P)$. Moreover, there exist two sets of vertices of $Tr(P)$, $S_{Tr(P)}^-$ and $S_{Tr(P)}^+$ of size 11 and 12 respectively, such that the following holds:*

- The set $S_{Tr(P)}^-$ dominates all the vertices of $Tr(P)$ and separates all the pairs of $Tr(P)$ but no pairs in P .
- The set $S_{Tr(P)}^+$ dominates all the vertices of $Tr(P)$, separates all the pairs of $Tr(P)$ and all the pairs in P .

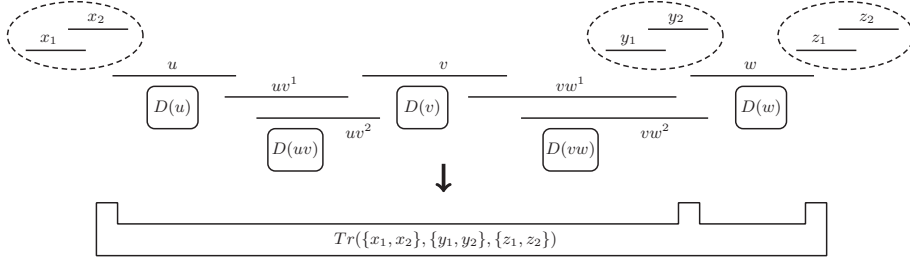

Fig. 2. Transmitter gadget $Tr(\{x_1, x_2\}, \{y_1, y_2\}, \{z_1, z_2\})$ and its “box” representation.

2.2 The main reduction

We now describe the reduction. Each element $x \in A \cup B \cup C$ is modelled by a choice pair $\{f_x, g_x\}$. Each triple of \mathcal{T} is modelled by a triple gadget:

Definition 7 (Triple gadget). Let $T = \{a, b, c\}$ be a triple of \mathcal{T} . The triple gadget $G_t(T)$ is an interval graph consisting of four choice pairs $p = \{p_1, p_2\}$, $q = \{q_1, q_2\}$, $r = \{r_1, r_2\}$, $s = \{s_1, s_2\}$ together with their associated dominating gadgets $D(p)$, $D(q)$, $D(r)$, $D(s)$ and five transmitter gadgets $Tr(p, q)$, $Tr(r, s)$, $Tr(s, a)$, $Tr(p, r, b)$ and $Tr(q, r, c)$, where:

- $a = \{f_a, g_a\}$, $b = \{f_b, g_b\}$ and $c = \{f_c, g_c\}$;
- Except for the choice pairs, for each pair of intervals of $G_t(T)$, its two intervals intersect different subsets of $\{D(p), D(q), D(r), D(s)\}$;
- In each transmitter gadget $Tr(P)$ and for each choice pair $\pi \in P$, the intervals of π intersect the same intervals except for the vertices u, v, w of $Tr(P)$;
- The intervals of $V(G) \setminus V(G_t(T))$ that are intersecting only a part of the gadget intersect accordingly to the transmitter gadget definition and do not separate the choice pairs p , q , r and s .

An illustration of a triple gadget is given in Figure 3. We remark that p , q , r and s in $G_t(\{a, b, c\})$, are all functions of $\{a, b, c\}$ but to simplify the notations we simply write p , q , r and s .

The following claim is proved in Appendix A.1 using Claim 6.

Claim 8. Let G be a graph with a triple gadget $G_t(T)$ and S be a locating-dominating set of G . We have $|S \cap G_t(T)| \geq 65$ and if $|S \cap G_t(T)| = 65$, no choice pair corresponding to a , b or c is separated by a vertex in $S \cap G_t(T)$. Moreover, there exist two sets of vertices of $G_t(T)$, $S_{G_t(T)}^-$ and $S_{G_t(T)}^+$ of size 65 and 66 respectively, such that the following holds.

- The set $S_{G_t(T)}^-$ dominates all the vertices of $G_t(T)$ and separates all the pairs of $G_t(T)$ but does not separate any choice pairs corresponding to $\{a, b, c\}$.
- The set $S_{G_t(T)}^+$ dominates all the vertices of $G_t(T)$, separates all the pairs of $G_t(T)$ and separates the choice pairs corresponding to $\{a, b, c\}$.

Given an instance (A, B, C, \mathcal{T}) of 3-DIMENSIONAL MATCHING with $|A| = |B| = |C| = n$ and $|\mathcal{T}| = m$, we construct the interval graph $G = G(A, B, C, \mathcal{T})$

Fig. 3. Triple gadget $G_t(T)$ with $T = \{a, b, c\}$ together with the choice pairs of elements a, b and c . We recall that these choice pairs are not part of $G_t(T)$.

as follows.

- As mentioned previously, to each element x of $A \cup B \cup C$, we assign a distinct choice pair $\{f_x, g_x\}$ in G . The intervals of any two distinct choice pairs $\{f_x, g_x\}, \{f_y, g_y\}$ are disjoint and they are all in \mathbb{R}^+ .
- For each triple $T = \{a, b, c\}$ of \mathcal{T} we first associate an interval I_T in \mathbb{R}^- such that for any two triples T_1 and T_2 , I_{T_1} and I_{T_2} do not intersect. Then inside I_T , we build the choice pairs $\{p_1, p_2\}, \{q_1, q_2\}, \{r_1, r_2\}, \{s_1, s_2\}$. Finally, using the choice pairs already associated to elements a, b and c we complete this to a triple gadget.
- When placing the remaining intervals of the triple gadgets, we must ensure that triple gadgets do not “interfere”: for every dominating gadget D , no interval in $V(G) \setminus V(D)$ must have an endpoint inside D . Similarly, the choice pairs of each triple gadget or transmitter gadget must only be separated by intervals among u, v and w of its corresponding private transmitter gadget. For intervals of distinct triple gadgets, this is easily done by our placement of the triple gadgets. To ensure that the intervals of transmitter gadgets of the same triple gadget do not interfere, we proceed as follows. We place the whole gadget $Tr(p, q)$ inside interval u of $Tr(p, r, b)$. Similarly, the whole $Tr(r, s)$ is placed inside interval v of $Tr(p, r, b)$ and w of $Tr(q, r, c)$. One has to be more careful when placing the intervals of $Tr(p, r, b)$ and $Tr(q, r, c)$. In $Tr(p, r, b)$, we must have that interval u separates p from the right of p . We also place u so that it separates r from the left of r . Intervals uv^1, uv^2 both start in r_1 , so that u also separates uv^1, uv^2 without these intervals interfering with the ones of r . Intervals uv^1, uv^2 continue until after pair s . In $Tr(q, r, c)$, we place u so that it separates q from the right, and we place w so that it separates r from the right; intervals uv^1, uv^2, v lie strictly between q and r ; intervals vw^1, vw^2 intersect r_1, r_2 but stop before the end of r_2 (so that w can separate both pairs vw^1, vw^2 and r but without these pairs interfering). It is now easy to place $Tr(s, a)$ between s and a .

The graph $G(A, B, C, \mathcal{T})$ has $159m + 18n$ vertices and the interval representation described by our procedure can be obtained in polynomial time. We are now ready to state the main result of this section (the proof is in Appendix A.2).

Theorem 9. (A, B, C, \mathcal{T}) has a perfect 3-dimensional matching if and only if $G = G(A, B, C, \mathcal{T})$ has a locating-dominating set with $65m + 7n$ vertices.

Theorem 9 shows that LOCATING-DOMINATING SET is NP-complete for interval graphs. In fact, the constructed graph is also a permutation graph (see Appendix A.3 for details).

Corollary 10. LOCATING-DOMINATING SET is NP-complete for graphs that are both interval and permutation graphs.

2.3 Diameter 2 and consequence for METRIC DIMENSION

We now describe a self-reduction for LOCATING-DOMINATING SET for graphs with a universal vertex (hence, graphs of diameter 2), and a similar reduction from LOCATING-DOMINATING SET to METRIC DIMENSION.

Let G be a graph. Let $f_1(G)$ be the graph obtained from G by adding a universal vertex u and a neighbour v of u of degree 1. Let $f_2(G)$ be the graph obtained from G by adding two adjacent universal vertices u, u' and two non-adjacent vertices v and w that are only adjacent to u and u' . See Figure 4 for an illustration. One can show that $\gamma^{\text{LD}}(f_1(G)) = \gamma^{\text{LD}}(G) + 1$, and $\dim(f_2(G)) = \gamma^{\text{LD}}(G) + 2$ (the proofs are not very difficult and deferred to Appendix A.4).

Fig. 4. Two reductions for diameter 2.

Theorem 11. Let \mathcal{C} be a class of graphs that is closed under the graph transformation f_1 . If LOCATING-DOMINATING SET is NP-complete for graphs in \mathcal{C} , then it is also NP-complete for graphs in \mathcal{C} that have diameter 2.

Theorem 12. Let \mathcal{C} be a class of graphs that is closed under the graph transformation f_2 . If LOCATING-DOMINATING SET is NP-complete for graphs in \mathcal{C} , then METRIC DIMENSION is also NP-complete for graphs in \mathcal{C} that have diameter 2.

Since Theorems 11 and 12 can be applied to interval graphs and permutation graphs, Corollary 10 implies the following.

Corollary 13. LOCATING-DOMINATING SET and METRIC DIMENSION are NP-complete for diameter 2-graphs that are both interval and permutation graphs.

3 METRIC DIMENSION is FPT on interval graphs

We now prove that METRIC DIMENSION (parameterized by solution size) is FPT on interval graphs. The algorithm is based on dynamic programming over a path-decomposition. Due to lack of space, most of the technicalities are deferred to Appendix B, but we present the most important ideas.

Given an interval graph G , we can assume that in its interval model, all endpoints are distinct, and that the intervals are closed. We define two natural total orderings of $V(G)$ based on this model: $x <_L y$ if and only if the left endpoint of x is smaller than the left endpoint of y , and $x <_R y$ if and only if the right endpoint of x is smaller than the right endpoint of y . We will work with the fourth distance-power G^4 of the input graph G . One can show (see Proposition 20) that G^4 is an interval graph and has an interval model inducing the same orders $<_L$ and $<_R$ as G . Our algorithm will use dynamic programming on a *nice path-decomposition* of G^4 . The classic concepts of tree-decompositions and its “nice” variant, due to Kloks [25], are defined in Appendix B.2, as well as useful properties of a nice path-decomposition of an interval graph.

We now present the most crucial preliminary results necessary for our algorithm (the proofs are delayed to Appendix B.3). We first start with a definition related to the linear structure of an interval graph that we will use extensively.

Definition 14. *Given a vertex u of an interval graph G , the rightmost path $P_R(u)$ of u is the path u_0^R, \dots, u_p^R where $u = u_0^R$, for every u_i^R ($i \in \{0, \dots, p-1\}$) u_{i+1}^R is the neighbour of u_i^R with the largest right endpoint, and thus u_p^R is the interval in G with largest right endpoint. Similarly, we define the leftmost path $P_L(u) = u_0^L, \dots, u_q^L$ where for every u_i^L ($i \in \{0, \dots, q-1\}$) u_{i+1}^L is the neighbour of u_i^L with the smallest left endpoint.*

Note that $P_R(u)$ and $P_L(u)$ are two shortest paths from u_0^R to u_p^R and u_q^L , respectively. We say that a pair u, v of intervals in an interval graph G is separated by interval x *strictly from the right* (*strictly from the left*, respectively) if x starts after both right endpoints of u, v (ends before both left endpoints of u, v respectively). In other words, x is not a neighbour of any of u and v .

The next lemma is crucial for our algorithm.

Lemma 15. *Let u, v, x be three intervals in an interval graph G and let i be an integer such that x starts after both right endpoints of $u_i^R \in P_R(u)$ and $v_i^R \in P_R(v)$. Then the three following facts are equivalent:*

- (1) x separates u_i^R, v_i^R ;
- (2) for every j with $0 \leq j \leq i$, x separates u_j^R, v_j^R ;
- (3) for some j with $0 \leq j \leq i$, x separates u_j^R, v_j^R .

A symmetric statement holds for $P_L(u)$.

We now define a *distance-2 resolving set* as a set S of vertices where for each pair u, v of vertices at distance at most 2, there is a vertex $x \in S$ such that $d(u, x) \neq d(v, x)$. Thanks to this local version of resolving sets, we will manage to “localize” the dynamic programming, as we will only need to distinguish pairs of vertices that will be present together in one bag.

Lemma 16. *Any distance-2 resolving set of an interval graph is a resolving set.*

The next lemma enables us to bound the size of the bags in our path-decomposition, which will induce diameter 4-subgraphs of G .

Lemma 17. *Let G be an interval graph with a resolving set of size k , and let $B \subseteq V(G)$ be a subset of vertices such that for each pair $u, v \in B$, $d_G(u, v) \leq d$. Then $|B| \leq 4dk^2 + (2d + 3)k + 1$.*

We are now ready to describe our algorithm.

Theorem 18. METRIC DIMENSION can be solved in time $2^{O(k^4)}n$ on interval graphs, i.e. it is FPT on this class when parameterized by the solution size k .

Proof. Let $(\mathcal{P}, \mathcal{X})$ be a path-decomposition of the interval graph G^4 obtained using Proposition 22. Our algorithm is a dynamic programming over $(\mathcal{P}, \mathcal{X})$.

Let t be a node of \mathcal{P} . We let $\mathcal{P}(X_t)$ be the set of pairs of X_t that are at distance at most 2 in G (by Lemma 16, these are the pairs that we need to separate). For each node t of \mathcal{P} , we compute a set of *configurations* using the configurations of the child of t in \mathcal{P} . A configuration contains full information about the local solution on X_t , but also stores necessary information about the vertex pairs that still need to be separated. More precisely, a configuration $C = (\mathbf{S}, \text{sep}, \text{toSepR}, \text{cnt})$ of t is a tuple where:

- $\mathbf{S} \subseteq X_t$ contains the vertices of the sought solution belonging to X_t ;
- $\text{sep} : \mathcal{P}(X_t) \rightarrow \{0, 1, 2\}$ assigns, to every pair in $\mathcal{P}(X_t)$, value 0 if the pair has not yet been separated, value 2 if it has been separated strictly from the left, and value 1 otherwise;
- $\text{toSepR} : \mathcal{P}(X_t) \rightarrow \{0, 1\}$ assigns, to every pair in $\mathcal{P}(X_t)$, value 1 if the pair needs to be separated strictly from the right (and it is not yet the case), and value 0 otherwise;
- cnt is an integer counting the total number of vertices in the partial solution that has led to C .

Starting with the leaf of \mathcal{P} , for each node our algorithm goes through all possibilities of choosing \mathbf{S} ; however, sep , toSepR and cnt are computed along the way. At each new visited node t of \mathcal{P} , a set of configurations is constructed from the configuration sets of the child of t . The algorithm makes sure that all the information is consistent, and that configurations that will not lead to a valid resolving set (or with $\text{cnt} > k$) are discarded.

The most crucial point of the algorithm is to use Lemma 15 to “localize” the problem by reducing it to separating pairs inside the current bag X_t . More precisely, for each pair $u, v \in \mathcal{P}(X_t)$, we can deduce from $\text{sep}(u, v)$ and \mathbf{S} whether u, v are already separated from a previous step of the algorithm or by a solution vertex of $\mathbf{S} \subseteq X_t$. If this is not the case and if t is a forget node that forgets u or v , then the pair u, v needs to be separated from the right in a future step of the algorithm corresponding to a bag that does not contain the pair u, v . By Lemma 15, this will be done by separating some pair u_i^R, v_i^R (that will be present together in a bag considered later), and hence we can set $\text{toSepR}(u_1^R, v_1^R) = 1$. The algorithm will then make sure that u_i^R, v_i^R are separated from the right by carrying over this constraint until it is met, along $P_R(u)$ and $P_R(v)$.

The final step of the algorithm simply consists in checking whether, at the root node, we obtained a configuration with $\text{cnt} \leq k$. By Proposition 22(b), every bag of $(\mathcal{P}, \mathcal{X})$ is a clique of G^4 (i.e. a subgraph of diameter at most 4

in G) and hence by Lemma 17, it has $O(k^2)$ vertices. Since there are $2^{O(|X_t|^2)}$ configurations for a bag X_t and all computations are polynomial-time in terms of $|X_t|$, the running time is indeed $2^{O(k^4)}n$.

The full details of the algorithm are given in Appendix B.4. The correctness and running time of the algorithm are formally proved in Appendix B.5. \square

4 Conclusion

We proved that both LOCATING-DOMINATING SET and METRIC DIMENSION are NP-complete even for diameter 2-graphs that are both interval and permutation graphs. This is in contrast to related problems such as DOMINATING SET, which is linear-time solvable both on both classes. However, we do not know their complexity for unit interval graphs or bipartite permutation graphs. We also note that our reduction can be adapted to related problems such as IDENTIFYING CODE (see the full version of this paper [15]).

Regarding our FPT algorithm for METRIC DIMENSION on interval graphs, we do not know whether the result holds for graph classes such as permutation graphs or chordal graphs. The main obstacles for adapting our algorithm to chordal graphs are (i) that Lemma 15, which is essential for our algorithm, heavily relies on the two orderings induced by intersection models of interval graphs, and (ii) that Lemma 16 is not true for chordal graphs (see Appendix C).

Acknowledgments. We thank Adrian Kosowski for helpful discussions.
